

A book of Practical Assignments for Psy309 at
UTM Fall 2024

Contents

About

This is a series of assignments intended to help third year UTM students transfer their theoretical knowledge of using the general linear model from Psy201/202 to a computational approach in **Rstudio**.

- 5 “practical” assignments help students to refine a research question, then generate fictitious data to represent their hypothesized effect.
- The final project involves synthesis of the practical assignments with additional analyses (3-way ANOVA and multiple linear regression).
- As they complete the assignments, students learn to think critically about research design and construct operationalization. They also develop basic coding skills, which are combined with their theoretical understanding of statistics in the final written assignment.

Chapter 1

Asking Scientific Questions and Literature Review

Overview

The purpose of this assignment is to showcase your interest in a specific topic related to psychology, and to demonstrate your ability to find **scholarly sources** that make claims related to your topic.

Your submission should not be longer than 2 pages (including references)

1. Choose a Research Topic in Psychology

In a single paragraph (3-5 sentences), tell us what you would like to research.

Some questions that you could think over while selecting a topic:

Why did you decide to study Psychology? There is some mystery about the mind, or some insight that you have had, that motivates you. Do you want to help people with a particular set of challenges? Do you want to understand growth and development? The way the brain works? How people interact? The possibilities are endless.

In this course you will learn how to develop a research proposal around a topic of your choice, one that could be the beginning of a grant proposal or a way to wow potential supervisors for grad school, or to impress potential employers who want to know if you can lead project. The more you make this something relevant to your own goals, the more useful this course will be.

It must be a topic in *psychology*: i.e., the study of the mind, and it should be something that can be studied *scientifically*, i.e., observed in such a way that other people could replicate your process and generate similar data. This topic will be the basis for your research project over the course of the semester, so please give it some thought!

2. See What's Out There

Go to the library PsycINFO page, Google Scholar, or similar academic search engine.

Conduct a basic search for a topic that you are interested in. If you would like more information about this process, we have multiple videos on conducting a literature search available online.

Please write a few paragraphs describing:

- The search engine(s) that you used
- What were the *specific* search terms you used (so if we entered those terms, we should get the same output as you)
- How did you expand / change your search terms to focus on the types of studies you were most interested in?
- Provide a reference list of 3-5 peer-reviewed, academic research papers on your research topic; the references should be listed in APA format.
- At least one of your papers must be an empirical paper!

Provide a brief (3-5 sentence) summary of one empirical, peer-reviewed research paper from your list (preferably one that represents an approach to your research topic that you find interesting.)

- Tell us what the paper was about and why you chose it - how did you know it was an empirical paper? What about it was interesting to you?
 - You don't have to tell us everything about the paper- again just a 3-5 sentence summary in your own words, which means you must leave many details out! You will get into the details of this paper in the next two practical assignments. Note: you can change this 'focus paper' later if you find something better, but it is better to start with a specific paper in mind.
 - You will end up having to create an empirical research proposal by the end of the term, so this paper can be an important example for you to rely and build upon as the term goes on. The important thing

is to pick a paper and dive in - this is a 'safe space' to just immerse yourself in a research approach, regardless of whether you actually perform research like this in the future!

3. Reflect

Write a closing paragraph (3-5 sentences) describing what it was like to try to find research on your topic.

- Was it hard to pick a topic? Did your topic change based on what you found (or couldn't find) during your literature review? What advice would you give to other students doing this assignment in the future?

Chapter 2

Exploring Types of Measurement in Research

Unlike other ways of knowing (epistemologies), the scientific method requires that we specify a way of measuring things in the world. It is important that the specified set of methods is described in such a way that other people could *replicate* the experiment, assuming that they have access to the necessary resources and training.

1. Identify dependent variable(s)

Think back to your submission from practical #1 (where you selected a general research topic and found some articles, with at least one of the articles performing empirical measurement).

Remind us about the research topic that you have chosen to focus on. This time, **use a *single sentence* that cites the empirical article in APA style**. Please also provide the full citation for the paper as well, in APA format (make sure that the components of the citation are written using APA standard, but **do not worry** about formatting the citation with a hanging indent).

For example:

On the topic of factors people's enjoyment of meditation, researchers have observed that while most people expect to enjoy breath-focused meditation more than visualization or mantra practices, but approximately half of all participants change their minds after trying all three practices (Anderson & Farb, 2018).

Anderson, T., & Farb, N. A. (2018). Personalizing practice using preferences for meditation anchor modality. *Frontiers in psychology*, 9, 1-10.

Describe the primary dependent variable in the research paper. Remember that a *dependent variable* is something that is observed (or measured), and is outside of the researcher's direct control (i.e., the dependent variable is not manipulated). If your paper has multiple dependent variables, you can mention that, but please tell us which variable you consider to be the most important.

2. Identify claim(s) made by the paper

One of the main reasons that we measure things is to make a claim about a broader population or about future events. Remember that the three main types of claims we make are: *frequency*, *association*, or *causal* claims. Make sure that you connect the DV to the IV(s) here to explain the parameters of the research finding.

Describe which of the three claims is / are being made in the paper that you outlined above and explain how you know (i.e., your reasoning). Could the DV be used to make the other two types of claims? What sort of study would be needed for each?

3. Critically Evaluate the Measurement Approach

In class and in the textbook, we have begun to explore the idea that not all measures are equally *valid* and *reliable* for making inferences. We discussed four forms of validity in class: construct, statistical, internal, and external.

Consider the validity of the empirical paper that you have selected. Please **define each of the four validities in your own words** using 1-2 sentences each. Then **write 3-4 sentences discussing the validity of the paper**. You may not feel super confident on the statistical validity, but you can discuss the others. For example, does the dependent variable accurately represent the construct that you are interested in exploring? Does the way they studied the construct make sense? Do the data come from a sample that has a good chance of generalizing to other people and other situations?

4. Develop a Research Idea

Now that you have reviewed the kinds of studies that are published in your field of interest and taken a look at the types of variables they use, expand on the

existing work. **Write 2-3 paragraphs describing a novel study idea** that would produce data to support at least two of the “types of claims” that we have discussed in class (e.g., Frequency AND Association). Make sure that you clearly describe the independent and dependent variables in the study.

What ideas do you have, either about re-using a measure you’ve read about, or improving / creating a new measure to investigate your topic? What sort of inference are you hoping to make? To describe something that we know little about? To look at the relationship between two or more constructs? Or to show that changing something about the situation causes changes in your dependent variable?

Please specify the **rationale** for the study (why would this research be important?), the **primary research question** (what is the primary thing these data will tell you?) and the **hypothesis** / **predicted results** (what sort of results are you predicting and WHY?).

5. Reflect

Write a closing paragraph (3-5 sentences) describing how you are thinking about measuring the construct of interest in your research topic. Remember that we will be creating and analyzing fictitious data over the next few weeks to further explore the research process. Would the study that you are conceptualizing be feasible in the real world? Why or why not? What processes would you need to follow in order to actually conduct this study (e.g., REB approval..)

Submissions should be 2-3 pages in length. References don’t need to be written on a separate page. No marks for APA format, so please feel free to make use of various levels of headings to enhance readability.

Chapter 3

Magnitude of Manipulations

1. Experiments: Manipulating Independent Variable(s)

If we want to go further from just showing an association to establishing that one construct directly influences or *causes* changes in another, we need to do experiments. In an experiments, we *manipulate* one variable to see if those unpredictable/independent manipulations create predictable effects on the dependent variable.

Think of a way in which you could manipulate an independent variable to create changes in your dependent variable of interest. In a short paragraph (3-5 sentences):

- Discuss your idea for how you could manipulate one thing (the independent variable) to change the dependent variable.
- Be clear on the direction of manipulation, e.g., if one increases how much an assignment is worth, a student's nervous level will also increase
- Provide an in-text citation to (at least) one peer-reviewed article that shows that the constructs might be related. If you can't find evidence of the exact same manipulation, show an association and describe how you could change it into a manipulation, or show how the manipulation has been used in another context but could be applied here.
- If there is no direct evidence or reporting of this relationship, then cite an article that shows that these constructs could be related.

- Below the paragraph, provide an APA style reference to the paper that you cited.

2. Proposed Magnitude of the effect of your IV on the DV

When designing an experiment, the **predicted magnitude of an effect** is a key factor, as this can be used to determine the most appropriate amount of participants (the larger the proposed effect, the fewer participants would be needed to detect it).

Based on your literature searches, how big of an effect are you predicting the experimental manipulation that you outlined above would produce on the DV of interest?

- Using numeric values and descriptive language, **explain the predicted magnitude of your proposed IV on the DV of interest.**
- A good place to start would be to review findings using your DV in the literature. How varied are responses using your chosen measure? Do participants usually respond / perform in consistent ways? Or is there a lot of variability in responses? Do different studies that report this measure have similar mean values in their control groups? Understanding how much spread of scores you might expect to see in your control condition could help you think critically about what you would expect data from your experimental group to look like.
- Remember, that the magnitude of the effect does not determine the importance of your findings - many important findings from the field of psychology involve quantification of small effects.
- Use at least one peer-reviewed reference to support the proposed magnitude of the relationship between your IV and DV.

3. Connect the theory to computation in R!

Generate an example mock data set that includes the variables that you described in part 2 (above) with 100 participants per group. **Print out a nice looking table that shows the n, mean, min, max, and standard error of the mean** for the key dependent variable that you are interested in measuring. Make sure that your table is organized to show these descriptive statistics for each of the experimental conditions that you proposed in part (2) above.

- Creating a reproducible data set will require using functions in **Rstudio**. For this reason ***this assignment must be generated using Rstudio.***
- Make sure to watch Jennet's videos (on Quercus) about how to generate data and tables through **Rstudio**.
- Make sure that you have `echo = TRUE`, `warning = FALSE`, `message = FALSE` set for your code blocks so that the output shows your code, but not the messages or warnings that R sends (and watch the tutorial video to get info on what this means).
 - Don't print the whole data-set that you've created in-line, or your output document will be really long.

4. Reflect

Write a closing paragraph (3-5 sentences) summarizing what it is like learning to work with R and what it is like to see all the variables visualized. What questions and/or difficulties have arisen? Do you think it is helpful to be able to simulate your data ahead of time? What do you think about the group size of $n = 100$ (e.g., should it be increased or decreased?).

Additionally, feel free to reflect on the process of using Rstudio to generate data - Is there anything that would have improved your experience doing this lab?

Code For Practical #3

```
# this is the "setup" chunk. Info here will apply to all code blocks in the document.
knitr::opts_chunk$set(echo = TRUE, # Show the code
                      warning = FALSE, # Hide warnings from R
                      message = FALSE) # Hide messages from R
```

```
# step 1 install packages
## Do once per computer

# install.packages(c("tidyverse", "reshape2"))

# Call the packages
## Do this every session

library(tidyverse) # Call the tidyverse
library(reshape2) # Call reshape2 (for the "melt" function)
```

Object-oriented programming

Examples of how Rstudio can be used to assign single values, lists of values, or 2-D arrays of Data.

```
# Notes

# text will cause problems

# First example
67 * 88

## [1] 5896

# Object-oriented programming

a <- 67 * 88 # Assign the result of the function onto the object "a"

# Example 2
b <- c(1,2,3,4,5) # Assign a list onto the object "b"

# Example 3 - DATA FAME
c <- data.frame( # Assign a 2-D data frame onto the object "c"
  ID = c(1,2,3,4,5),
  Score = c(100,110,90,95,107)
)
```

Random number generation

```
set.seed(123) # Beginning of the random process

d <- data.frame(
  ID = c(1:100), # 100 IDs
  Score = runif(n=100,min=1,max=10) # 100 random scores
)

head(d) # show me the first 6 rows

##      ID      Score
```

```
## 1  1 3.588198
## 2  2 8.094746
## 3  3 4.680792
## 4  4 8.947157
## 5  5 9.464206
## 6  6 1.410008
```

```
tail(d) # show me the last 6 rows
```

```
##      ID      Score
## 95  95 3.883359
## 96  96 2.689220
## 97  97 8.040649
## 98  98 1.842355
## 99  99 5.201011
## 100 100 5.603549
```

```
# Make a quick histogram of the data
histogram <- d %>%
  ggplot(aes(x=Score))+
  geom_histogram(bins = 8, alpha=0.2, colour = "black")+
  theme_classic()

# Save the histogram as a high quality .png image
ggsave("Figs/hist_1.png",histogram,height = 2.5, width = 5, dpi = 300)

# Call back the high quality image
knitr::include_graphics("Figs/hist_1.png")
```

Sample from the normal distribution

```
e <- data.frame(  
  ID = c(1:100),  
  Score = rnorm(n = 100, mean = 100, sd = 15) # sample from normal distribution  
)  
  
# Generate the chart  
histogram <- e %>%  
  ggplot(aes(x=Score))+  
  geom_histogram(bins = 8, alpha=0.2, colour = "black")+  
  theme_classic()  
  
# Save the histogram as a high quality .png image  
ggsave("Figs/hist_2.png",histogram,height = 2.5, width = 5, dpi = 300)  
  
# Call back the high quality image  
knitr::include_graphics("Figs/hist_2.png")
```

Sampling from a list of values

```
# Example 1: sample randomly from the values 1:7  
f <- data.frame(  
  ID = c(1:100),  
  Score = sample(x=c(1:7),size=100,replace = TRUE)  
)
```

```

# Example 2: set the probabilities for the possible responses
Prob_info <- c(0.02, 0.03, 0.05, 0.1, 0.1, 0.4, 0.4)

g <- data.frame(
  ID = c(1:100),
  Score = sample(x=c(1:7),size=100,replace = TRUE,prob = Prob_info) # use prob info
)

# Generate the chart
histogram <- g %>%
  ggplot(aes(x=Score))+
  geom_histogram(bins = 7, alpha=0.2, colour = "black")+
  theme_classic()+
  scale_x_continuous(breaks=c(1:7))

# Save the histogram as a high quality .png image
ggsave("Figs/hist_3.png",histogram,height = 2.5, width = 5, dpi = 300)

# Call back the high quality image
knitr::include_graphics("Figs/hist_3.png")

```

Example of a complete dataset

```

# Make data for a ctl group
Control_group <- data.frame(

```

```

ID = c(1:100),
Condition = "Placebo",
Baseline_IQ = rnorm(n=100,mean=100,sd=15),
Post_IQ = rnorm(n=100,mean=100,sd=15)
)

# And experimental data with the exact same column headers
Experimental_group <- data.frame(
  ID = c(101:200),
  Condition = "Drug",
  Baseline_IQ = rnorm(n=100,mean=100,sd=15),
  Post_IQ = rnorm(n=100,mean=130,sd=15)
)

# attach them together
JLB_data <- rbind(Control_group,Experimental_group)

```

Aggregate table of data

```

# An example of "tidy text" (from the tidyverse):
table <- JLB_data %>% # Take the data AND THEN
  melt(id.vars = c("ID","Condition")) %>% # Switch to long form AND THEN
  group_by(Condition,variable) %>% # Group by the IVs
  summarise( # Calculate descriptive stats
    n = n(),
    mean = mean(value),
    sd = sd(value),
    min = min(value),
    max = max(value)
  ) %>% mutate(se = sd / sqrt(n)) # Create a column for SE, and compute it

# Rename the columns for a better looking table
colnames(table) <- c("Condition","Timepoint","n","mean","sd","min","max","se")

# a regular table
table

## # A tibble: 4 x 8
## # Groups:   Condition [2]
##   Condition Timepoint      n mean  sd  min  max   se
##   <chr>      <fct>    <int> <dbl> <dbl> <dbl> <dbl> <dbl>
## 1 Drug      Baseline_IQ    100  96.8  13.9  63.1  137.  1.39
## 2 Drug      Post_IQ       100  131.   14.7  84.3  176.  1.47

```

```
## 3 Placebo   Baseline_IQ   100  99.3  14.5  67.9  137.  1.45
## 4 Placebo   Post_IQ       100  98.9  15.8  54.4  136.  1.58
```

```
# a pretty table
knitr::kable(table)
```

Condition	Timepoint	n	mean	sd	min	max	se
Drug	Baseline_IQ	100	96.79806	13.87755	63.13986	136.5700	1.387755
Drug	Post_IQ	100	131.05099	14.66883	84.29550	175.8569	1.466883
Placebo	Baseline_IQ	100	99.33318	14.50270	67.89372	136.8935	1.450270
Placebo	Post_IQ	100	98.91235	15.79230	54.43327	135.5055	1.579230

Please submit a single document for practical #4. A .docx file is the preferred format.

Chapter 4

Correlation Statistics and Plots

1. Thinking About Association

As part of your final paper, you will be proposing an association between your dependent variable (DV) and a covariate of interest. In the last practical assignment, you developed some ‘priors’ around what the DV and covariate would look like. In this assignment, you will be asked to justify, simulate, and report the association between your DV and your covariate.

The first step is to **write an introductory paragraph** that reminds us what your proposed DV and covariate are, and why you believe they should be associated. You can cite papers later- first just explain how you think the two variables work together. For example, if the your DV were “feelings of stress” and your covariate were “optimism”, tell us a bit about the relationship between them from a theoretical perspective- do optimistic people tend not to perceive stressful life events the same way? Perhaps optimistic people just don’t experience the same level of physiological reaction to stressors and see the world a less threatening place? Help us understand why you think these variables ought to be related, or at least why it is possible that they are.

2. What is already known about these variables?

Write a paragraph or two describing what we know about your proposed DV and covariate. What direction are the proposed associations? In this section, you should cite at least 2 empirical, peer-reviewed papers that help

you to estimate the expected association size, using APA format (minus hanging indents) and including the full references below the paragraph(s).

Most importantly, we need to get specific about the expected association value. In your brief literature review, please report any measure of association, which will often be a correlation (r) or beta estimate (b), along with some interpretation of the effect size involved. Effect sizes can be described by specific effect size statistics like Cohen's d or partial η^2 , or they could be described by confidence intervals.

If you cannot find any reports of correlation values in the literature, then you will have to argue from theory about your predicted effect size:

Table 1 Values of Effect Sizes and Their Interpretation

<i>Kind of Effect Size</i>	<i>Small</i>	<i>Medium</i>	<i>Large</i>
r	.10	.30	.50
d	0.20	0.50	0.80
η^2_p	.01	.06	.14
f^2	.02	.15	.35

Source: Cohen, J. (1992). A power primer. *Psychological Bulletin*, 112, 155–159. doi:10.1037/0033-2909.112.1.155

Please note that finding correlations $>.30$ (or $<-.30$) is rare in a lot of psychology (especially human research; animal studies tend to yield larger effect sizes), so you will need to justify the effect size you expect to find.

3. Power Analysis: what sample size should you use?

For this portion of the assignment, make sure that you have your code blocks set to `echo = TRUE`, `message = FALSE`, `warning = FALSE`. This will print the code and the result, but not excessive the messages that R sends.

Use an online calculator (link in Lecture_5 slides to my favorite one, but there are many available) to estimate the sample size needed given the estimated correlation that you derived from your literature search.

4. A picture is worth 100 words...

Simulate two columns of data to represent your DV and covariate. Use the sample size that you determined was required for adequate power.

Generate a ggplot (scatterplot) of the data with a linear line of best fit. You can format this graph in any way that you see fit. Feel free to be creative! Every element of this chart can be tweaked to your specifications. Feel free to [Google](#) how to change specific aesthetics.

Save the ggplot as a high-quality .png image (`dpi = 300`), and call back the high quality image for your assignment. Add a figure caption to describe the relationship that you have depicted in the chart.

Call back the image that you saved to showcase your simulated data in pictorial form!

5. Reflect

Write a closing paragraph (3-5 sentences) summarizing what it is like trying to estimate an association / correlation from the literature. What did you think about creating your first data visualization using R? Were you surprised by the number of participants required to detect your effect with 80% power? Feeling confused about any of these concepts? Is there anything that would have improved your experience doing this assignment?

Code for Practical #4

```
# Set up how the code chunks will print
knitr::opts_chunk$set(echo = TRUE, # Show the code
                      warning = FALSE, # Hide the warnings
                      message = FALSE) # Hide the messages
```

Generate Data

```
# You must install packages before you can use them.
# You only need to install once per computer.

# install.packages(c("faux", "tidyverse")) # Remove leading hashtag to run this line!
```

```

# Once the packages are installed, you can load them to your current R session using
library(faux)
library(tidyverse)

# Set a consistent start point for "random" data generation
# Makes it so the output will be consistent

set.seed(123) # Can be any value.

# Generate data. Specify the number of rows, number of variables, means for the columns

data <- rnorm_multi(n = 85, vars = 2, mu = c(65,100), sd = c(10,15), r = -0.3)

```

Check out the data

```

# Show me the first 6 rows of data:
head(data)

```

```

##           X1           X2
## 1 64.74322  90.80306
## 2 56.44198  93.49663
## 3 53.76554 121.72313
## 4 67.53304 101.96359
## 5 54.27693  98.64371
## 6 48.10980 122.44146

```

```

# Rename the columns to represent your variables
colnames(data) <- c("Age", "IQ")

```

Check the correlation

```

# Check the correlation between the two columns
# If you don't like it, play around with the value in set.seed until you are happy.
cor.test(data$Age, data$IQ)

```

```

##
## Pearson's product-moment correlation

```

```
##
## data: data$Age and data$IQ
## t = -2.5503, df = 83, p-value = 0.0126
## alternative hypothesis: true correlation is not equal to 0
## 95 percent confidence interval:
## -0.45646873 -0.05988606
## sample estimates:
## cor
## -0.2695696
```

Code to generate a basic scatterplot:

```
basic <- data %>%
  ggplot(aes(x = Age, y = IQ))+
  geom_point()+
  geom_smooth(method = "lm")

# Save a high quality .png image
## Default size is 7 inches x 7 seven inches
ggsave("Figs/scatter_1.png",basic, dpi = 300)

# Call back the high quality image
knitr::include_graphics("Figs/scatter_1.png")
```

A fancier, better looking scatterplot:

```
a <- data %>%
  ggplot(aes(x = Age, y = IQ))+
  geom_point(size = 4, alpha = 0.5, colour = "#800020")+
  geom_smooth(method = "lm", colour="#800020", fill="#800020")+
  theme_classic()+
  theme(plot.title = element_text(hjust=0.5))+
  labs(
    x = "Age of Participants",
    y = "IQ Score",
    title = "Relationship Between Age and IQ"
  )+
  xlim(30,90)+
  ylim(60,140)
```

```
# Save the chart once you're happy with it as a high quality .png image  
ggsave("JLB_graph.png",a,height=4,width=4,dpi = 300)  
  
# Add in the high quality image saved above  
knitr::include_graphics("JLB_graph.png")
```

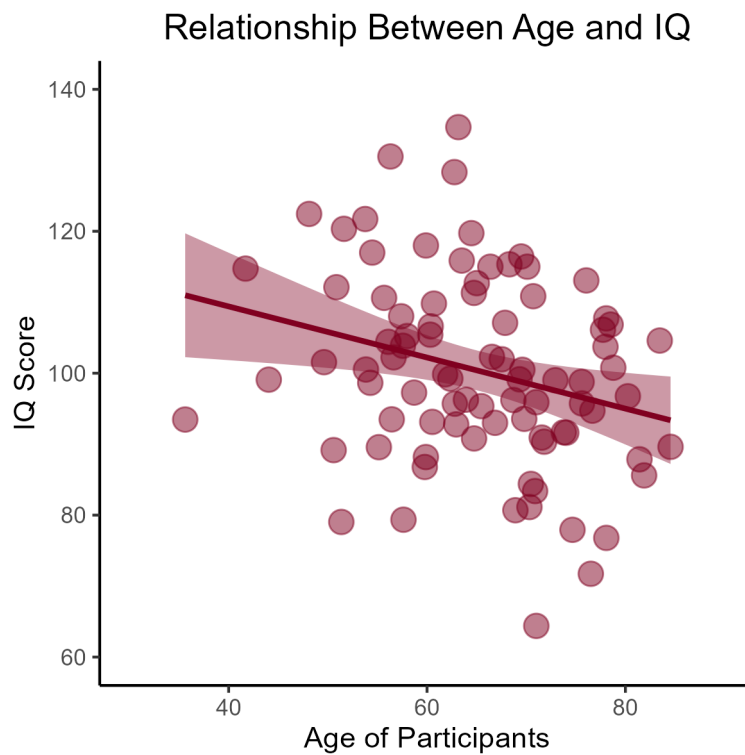

Figure 4.1: ADD A FIGURE CAPTION HERE

Chapter 5

Connecting the IV and Covariate

1. Thinking About Causality

Strength of association is a necessary step in determining whether there is a causal relationship between X and Y, but it is not sufficient for inferring causality. For your final assignment, you will be designing an experiment that involves at least 2 independent variables (The “IV” and the “covariate” that you have explored in the previous assignments).

In prior assignments, you were already asked to provide a simple group comparison or manipulation (an IV) that could reveal a difference in your DV. Now, please **write a paragraph explaining this decision in more detail** - what is the theory or explanation for why this manipulation works?

2. What is already known?

The second step is getting back into literature review. **Write a paragraph or two** in APA format describing what we know about your proposed manipulation and DV. What in the research literature (citing 2-3 papers) makes you believe that this manipulation will influence your DV? What direction is the proposed effect, i.e., does the manipulation increase or decrease your DV.

Most importantly, we need to get specific about the expected change in the DV when you manipulate the IV. In your brief literature review, please report any measure of effect size, which will often be a cohen’s d or partial eta-squared (2) or beta estimate (b). Best of all would be to see how much of a change in the DV in units of the DV the manipulation makes.

3. Connect the theory of the IV-DV relationship to your proposed covariate.

Explain how the continuous covariate might modulate the relationship between the IV and DV that you are proposing. Use literature to support your ideas. Be very clear about the proposed direction of the effects. Would you expect the IV to affect all levels of the covariate equally? Why or why not?

Reference at least one article that suggests a relationship between your **independent variable** and **proposed covariate** to support your narrative.

4. Transform the continuous covariate to a categorical variable

Using the r-code that you developed in practical 4, have a look at your continuous covariate and continuous DV. Imagine that this continuous relationship represents the real-world construct. If you were to divide this continuum into categories, how many would you use and why? Explain why it might make sense to use this number of categories (either from a statistical or a theoretical perspective).

Back to the code! Using the data that you simulated in practical 4, transform the continuous covariate into a new column that is categorical. Use ggplot to make a bar chart with error bars that represent the standard error of the mean and individual points to represent your theoretical participants' scores on the DV. Use the method that we learned in practical 4 to save off a high quality .png image of this chart, then call it back using knitr::kable().

Compute a statistical analysis to measure whether the categories that you selected differ significantly from one another on your DV. This analysis should either be a two-sample t-test or a one-way ANOVA (depending on the number of categories you chose). Interpret the analysis using an APA statement.

Make sure that you have `echo = TRUE`, `warning = FALSE`, `message = FALSE` set for your code blocks so that R will print out your code and the results, but will hide messages and warnings.

5. Reflect

What are the advantageous and disadvantages to transforming the continuous covariate into a categorical variable? Was it difficult to choose the number of categories to divide your covariate into? What did you think about generating a bar chart through ggplot? How did running your first statistical analysis through

R go? Is there anything that would have helped you learn these processes more effectively? Any lingering questions?

Code for Practical #5

```
# Set up how the code chunks will print
knitr::opts_chunk$set(echo = TRUE, # Show the code
                      warning = FALSE, # Hide the warnings
                      message = FALSE) # Hide the messages

library(faux)
library(tidyverse)
```

Generate data

The block of code below is the same as what was computed in practical #4. Here, the theory is to generate two columns of data of a given n (i.e., number of rows) with an approximate correlation between the columns specified. The two columns should represent your chosen covariate and dependent variable.

```
# Set a consistent start point for "random" data generation
# Makes it so the output will be consistent

set.seed(123) # Can be any value.

# Generate data. Specify the number of rows, number of variables, means for the columns, sd's for
data <- rnorm_multi(n = 85, vars = 2, mu = c(65,100), sd = c(10,15), r = -0.3)

# Rename the columns to represent your variables
colnames(data) <- c("Age", "IQ")

##### Everything above this point is copy & pasted from practical #4.
```

Transform

Generate a 3rd column of data that will represent a categorized version of the covariate. Divide the participants into categories based on specified cut points.

```
# Transform the continuous variable into categories
data$age_cat <- cut(data$Age,
                    breaks = c(-Inf, 65, Inf), # cut points
                    labels = c("Under 65", "Over 65")) # labels

head(data) # Check out the data frame with the new column
```

```
##      Age      IQ age_cat
## 1 64.74322 90.80306 Under 65
## 2 56.44198 93.49663 Under 65
## 3 53.76554 121.72313 Under 65
## 4 67.53304 101.96359 Over 65
## 5 54.27693 98.64371 Under 65
## 6 48.10980 122.44146 Under 65
```

Make a Bar Graph

```
# A bar graph
a <- data %>%
  group_by(age_cat) %>%
  summarise(
    n=n(),
    mean=mean(IQ),
    sd=sd(IQ)
  ) %>% mutate(se=sd / sqrt(n)) %>%
  ggplot(aes(x=age_cat,y=mean, colour = age_cat, fill= age_cat, shape=age_cat)) +
  geom_bar(stat="identity",alpha=0.2)+
  geom_errorbar(aes(x=age_cat,ymin=mean-se,ymax=mean+se),width=0.5)+
  geom_jitter(data = data,aes(x=age_cat,y=IQ),height=0, width=0.25, size=3,alpha=0.5)+
  scale_colour_manual(values = c("grey","black"))+
  scale_fill_manual(values=c("grey","black"))+
  theme_classic()+
  theme(legend.position = "none")+
  theme(plot.title = element_text(hjust=0.5))+
  labs(
    x="Age Categories",
    y="IQ Score",
    title="Effect of Age on \n IQ Scores"
  )

ggsave("2_bars.png",a,height=4,width=3,dpi=300)

knitr::include_graphics("2_bars.png")
```

Figure 5.1: First example: Here, I divided the continuous covariate into two categories.

Analyze

Run a t-test because there are only two groups here.

```
# Levene's test for equity of variances
var.test(data = data, IQ ~ age_cat)
```

```
##
## F test to compare two variances
##
## data: IQ by age_cat
## F = 1.1772, num df = 41, denom df = 42, p-value = 0.6007
## alternative hypothesis: true ratio of variances is not equal to 1
## 95 percent confidence interval:
## 0.6359244 2.1842525
## sample estimates:
## ratio of variances
## 1.177203
```

```
# A t.test when variances are not unequal
t.test(data = data, IQ ~ age_cat, var.equal = TRUE)
```

```
##
## Two Sample t-test
##
## data: IQ by age_cat
## t = 2.8695, df = 83, p-value = 0.005214
## alternative hypothesis: true difference in means between group Under 65 and group Over 65
## 95 percent confidence interval:
## 2.462339 13.586680
## sample estimates:
## mean in group Under 65 mean in group Over 65
## 104.45180 96.42729
```

3-category example

```
# An example of how to divide the continuous variable into 3 categories
data$age_cat <- cut(data$Age,
  breaks = c(-Inf, 60, 70, Inf),
  labels = c("Under 60", "60-70", "Over 70"))

# Graph for the 3-category data
```

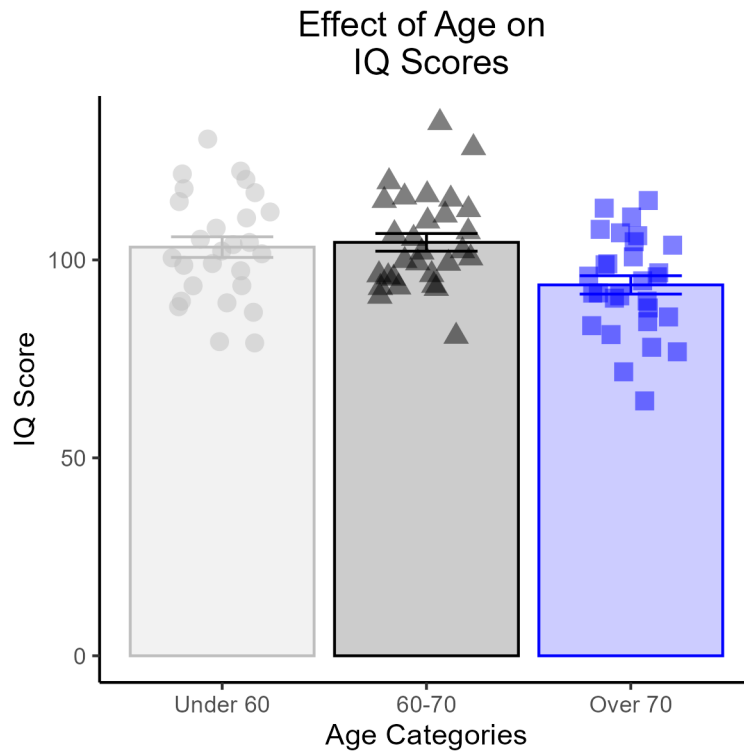

```

## Only change vs above is the number of colours! (Robust!!)
JLB_garph <- data %>% # Assign the chart to an object
  group_by(age_cat) %>%
  summarise(
    n=n(),
    mean=mean(IQ),
    sd=sd(IQ)
  ) %>% mutate(se=sd / sqrt(n)) %>%
  ggplot(aes(x=age_cat,y=mean, colour = age_cat, fill= age_cat, shape=age_cat)) +
  geom_bar(stat="identity",alpha=0.2)+
  geom_errorbar(aes(x=age_cat,ymin=mean-se,ymax=mean+se),width=0.5)+
  geom_jitter(data = data,aes(x=age_cat,y=IQ),height=0, width=0.25, size=3,alpha=0.5)+
  scale_colour_manual(values = c("grey","black","blue"))+
  scale_fill_manual(values=c("grey","black","blue"))+
  theme_classic()+
  theme(legend.position = "none")+
  theme(plot.title = element_text(hjust=0.5))+
  labs(
    x="Age Categories",
    y="IQ Score",
    title="Effect of Age on \n IQ Scores"
  )

# Save a high quality .png copy of the image
ggsave("JLB_prc_5.png",JLB_garph,height=4,width=4,dpi=300)

# Call back the high quality image
knitr::include_graphics("JLB_prc_5.png")

```

5.0.1 Analyze 3-category example

When there are more than two groups, use ANOVA instead of a t-test. If the results from the omnibus test of significance indicate $p < 0.05$, run Tukey's honestly significant difference test to figure out *where* the group differences are.

```
# Run a one-way ANOVA
res <- aov(data = data, IQ ~ age_cat)

# Follow up to find out which groups differ from one-another.
TukeyHSD(res)

##      Tukey multiple comparisons of means
##        95% family-wise confidence level
##
## Fit: aov(formula = IQ ~ age_cat, data = data)
##
## $age_cat
```

##		diff	lwr	upr	p adj
##	60-70-Under 60	1.205088	-6.882959	9.293134	0.9327115

Capstone Project: A Simulated Research Paper

Overview

The purpose of the practical assignments that you have completed across the term was to provide you with all of the tools needed to execute a fictitious experiment. Now, you will integrate these skills to produce your final written assignment.

The final assignment should demonstrate your understanding of research methodology, document generation using Rstudio and competency using R code. The goal of this project should be to produce an output document that you could present as a “portfolio piece” in an academic (or other) context.

For this reason, please **show code used to generate analyses** as well as the results from those analyses. **Hide code used to generate figures**, but show the results (aka the high-quality images). Please submit a single .docx file that was generated through Rmarkdwon as your submission.

Introduction

The expected length of the introduction section is ~ 1000 words. Make sure that you divide your ideas into paragraphs that each discuss a unique component of your study. The introduction section should be at least 5 paragraphs long, and should not be more than 10 paragraphs. We do not typically use subheading within the introduction section of an empirical article. You should introduce the articles that you have sourced throughout the practical assignments by describing **what’s been done**, **what’s been found**, and **what these findings means**. Use the past literature to provide rationale for the experiment that you are currently conducting.

In the final paragraph of the introduction section, you should explain the purpose of your paper (e.g., describe how you will be extending upon the findings

that you’ve summarized so far). Make sure that you clearly explain all of the variables you will be using: The independent variable, the dependent variable, and the covariate.

Methods

Divide your methods into “participants”, “materials”, “procedure”, “statistical analyses” (or similar) subheadings. Explain transparently that you will be simulating data using Rstudio to demonstrate the theoretical study that you have designed. Describe the method for determining your sample size and the final number of participants you will simulate. Provide descriptions of the methods and procedure so that an new reader that is knowledgeable about experimental design and Rstudio would be able to recreate your simulated experiment exactly.

Use code from Practical 4:

*# Set a consistent start point for "random" data generation
Makes it so the output will be consistent*

`set.seed(123)` *# Can be any value.*

Generate data. Specify the number of rows, number of variables, means for the column.

`data <- rnorm_multi(n = 85, vars = 2, mu = c(65,100), sd = c(10,15), r = -0.3)`

Rename the columns to represent your variables
`colnames(data) <- c("Age", "IQ")`
`head(data)`

```
##           Age           IQ
## 1 64.74322 90.80306
## 2 56.44198 93.49663
## 3 53.76554 121.72313
## 4 67.53304 101.96359
## 5 54.27693 98.64371
## 6 48.10980 122.44146
```

Do not worry about the length of your methods or results section, just take the space that you need to fully describe your experimental proceedings / findings.

Results

Divide your results section into subheadings that describe different statistical analyses. The results of the analyses should be printed in both versions of your submission. Center your figures and provide figure captions. Make sure that each figure has a label (e.g., Figure 1), and that each of the figures is referenced in-text.

Think about keeping your analysis strategy **succinct** and **logical**. You need to balance volume with importance - show you understanding of data storytelling by presenting the analyses clearly using simple, direct sentences. Think about the reader - make your series of outputs *as easy to follow as possible*.

Correlation Analysis

Analyze, interpret, discuss, and plot the continuous relationship between the covariate and the dependent variable (practical #4).

```
cor.test(data$Age,data$IQ)
```

```
##
## Pearson's product-moment correlation
##
## data: data$Age and data$IQ
## t = -2.5503, df = 83, p-value = 0.0126
## alternative hypothesis: true correlation is not equal to 0
## 95 percent confidence interval:
## -0.45646873 -0.05988606
## sample estimates:
## cor
## -0.2695696
```

One-Way Analysis

Explain, perform, graph, analyze, and interpret the transformation of the continuous covariate to a categorical variable (practical #5). Make sure that you are clear about the number of levels that you are using, and the rationale for this choice. Test whether there is a “basal” difference between the groups using the appropriate analysis (t-test or ANOVA) and interpret the results.

```
# Transform the continuous variable into categories
data$age_cat <- cut(data$Age,
                    breaks = c(-Inf, 65, Inf), # cut points
```

```

                                labels = c("Under 65", "Over 65")) # labels
head(data)

```

```

##           Age           IQ  age_cat
## 1 64.74322  90.80306 Under 65
## 2 56.44198  93.49663 Under 65
## 3 53.76554 121.72313 Under 65
## 4 67.53304 101.96359  Over 65
## 5 54.27693  98.64371 Under 65
## 6 48.10980 122.44146 Under 65

```

```

# Levene's test for equity of variances
var.test(data = data, IQ ~ age_cat)

```

```

##
## F test to compare two variances
##
## data:  IQ by age_cat
## F = 1.1772, num df = 41, denom df = 42, p-value = 0.6007
## alternative hypothesis: true ratio of variances is not equal to 1
## 95 percent confidence interval:
##  0.6359244 2.1842525
## sample estimates:
## ratio of variances
##           1.177203

```

```

# A t.test when variances are not unequal
t.test(data = data, IQ ~ age_cat, var.equal = TRUE)

```

```

##
## Two Sample t-test
##
## data:  IQ by age_cat
## t = 2.8695, df = 83, p-value = 0.005214
## alternative hypothesis: true difference in means between group Under 65 and group Over 65
## 95 percent confidence interval:
##  2.462339 13.586680
## sample estimates:
## mean in group Under 65  mean in group Over 65
##           104.45180           96.42729

```

Factorial ANOVA

Compute, interpret, and graph the results of the factorial ANOVA. Make sure that you run ALL of the appropriate follow-up comparisons, and explain what the results of each analysis means. You can graph the same data multiple ways if that helps tell the story of the various comparisons. Each project will look different - focus on conveying your data in the way that makes the most sense given your design.

```
## Generate Final Dataset:

set.seed(426)

# Split your data frame into data frames corresponding to your levels of the categorized covariate

Under_65 <- data[data$age_cat == "Under 65", ]
Over_65 <- data[data$age_cat == "Over 65", ]

# Randomly assign your independent variable to half the members of each group:

Under_65$Drug <- c(rep("Control",21), rep("Drug",21))
Over_65$Drug <- c(rep("Control",21), rep("Drug",22))

# Split the data frame by the experimental groups

Under_65_control <- Under_65[Under_65$Drug == "Control", ]
Under_65_drug <- Under_65[Under_65$Drug == "Drug", ]

Over_65_control <- Over_65[Over_65$Drug == "Control", ]
Over_65_drug <- Over_65[Over_65$Drug == "Drug", ]

# Create distributions of the proposed outcome after "intervention" (application of the IV)

Under_65_control$Post_IQ <- rnorm(n = 21, mean = 100, sd = 15)
Under_65_drug$Post_IQ <- rnorm(n = 21, mean = 100, sd = 15)

Over_65_control$Post_IQ <- rnorm(n = 21, mean = 90, sd = 10)
Over_65_drug$Post_IQ <- rnorm(n = 22, mean = 100, sd = 15)

final_data <- rbind(Under_65_control,Under_65_drug,Over_65_control,Over_65_drug)

head(final_data)

##           Age           IQ age_cat   Drug   Post_IQ
## 1 64.74322  90.80306 Under 65 Control 115.36923
```

```
## 2 56.44198 93.49663 Under 65 Control 131.36582
## 3 53.76554 121.72313 Under 65 Control 103.77843
## 5 54.27693 98.64371 Under 65 Control 95.39799
## 6 48.10980 122.44146 Under 65 Control 113.34786
## 7 57.98470 105.23238 Under 65 Control 116.07211
```

Aggregate your final data to check it out:

```
knitr::kable(final_data %>%
  group_by(Drug,age_cat) %>%
  summarise(
    n=n(),
    mean=mean(Post_IQ),
    sd=sd(Post_IQ)
  ) %>% mutate(se = sd / sqrt(n))
)
```

Drug	age_cat	n	mean	sd	se
Control	Under 65	21	100.20596	14.62407	3.191234
Control	Over 65	21	88.54052	12.04785	2.629057
Drug	Under 65	21	101.12417	16.27543	3.551591
Drug	Over 65	22	106.40972	13.09813	2.792530

Switch to long-form

```
long_data <- final_data %>%
  mutate(ID = c(1:85)) %>% # Add an ID column
  melt(id.vars=c("ID","Drug","age_cat","Age"))

head(long_data)
```

```
##   ID   Drug age_cat   Age variable   value
## 1  1 Control Under 65 64.74322      IQ 90.80306
## 2  2 Control Under 65 56.44198      IQ 93.49663
## 3  3 Control Under 65 53.76554      IQ 121.72313
## 4  4 Control Under 65 54.27693      IQ 98.64371
## 5  5 Control Under 65 48.10980      IQ 122.44146
## 6  6 Control Under 65 57.98470      IQ 105.23238
```

I'm making 2 graphs to show the same data two ways

You choose one way that makes the most sense given your design.

```
A <- long_data %>%
  group_by(age_cat,Drug,variable) %>%
  summarise(
    n=n(),
    mean=mean(value),
    sd=sd(value)
```

```

) %>% mutate(se = sd /sqrt(n)) %>%
ggplot(aes(x=variable,y=mean,colour=age_cat,shape=age_cat,group=age_cat))+
geom_point(size=4,alpha=0.5)+
geom_line(linewidth=1, alpha=0.5)+
geom_errorbar(aes(x=variable,ymin=mean-se,ymax=mean+se),width=0.5)+
geom_jitter(data = long_data,aes(x=variable,y=value),size=3,alpha=0.2,height=0,width=0.25)+
facet_wrap(~Drug)+
theme_classic()+
theme(legend.position = c(0,1),legend.justification = c(0,1))+
theme(legend.background = element_rect(fill="transparent"))+
ylim(50,150)+
labs(
  x="Time of Testing",
  y="IQ Score"
)

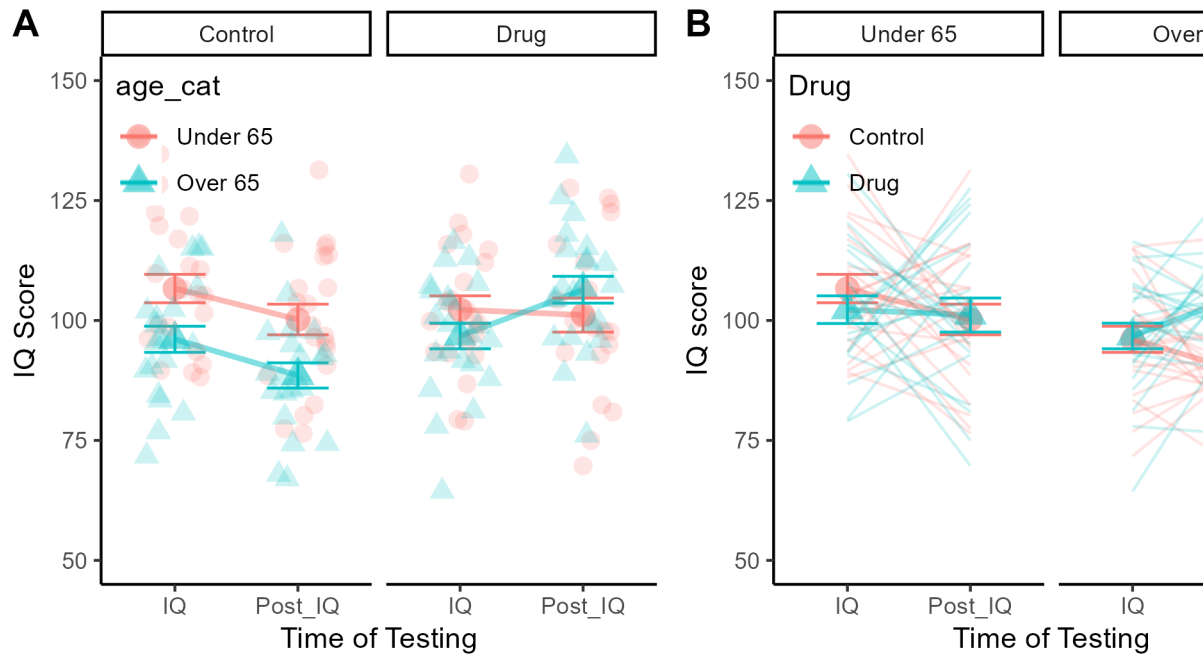

B <- long_data %>%
group_by(age_cat,Drug,variable) %>%
summarise(
  n=n(),
  mean=mean(value),
  sd=sd(value)
) %>% mutate(se = sd /sqrt(n)) %>%
ggplot(aes(x=variable,y=mean,colour=Drug,shape=Drug,group=Drug))+
geom_point(size=4,alpha=0.5)+
geom_line(linewidth=1, alpha=0.5)+
geom_errorbar(aes(x=variable,ymin=mean-se,ymax=mean+se),width=0.5)+
geom_line(data=long_data,aes(x=variable,y=value,group=ID),alpha=0.2)+
facet_wrap(~age_cat)+
theme_classic()+
theme(legend.position = c(0,1),legend.justification = c(0,1))+
theme(legend.background = element_rect(fill="transparent"))+
ylim(50,150)+
labs(
  x="Time of Testing",
  y="IQ score"
)

# Arrange the two graphs side-by-side for easy viewing / comparison.
panel <- ggarrange(A,B,
  labels=c("A","B"))

# Save & call back
ggsave("graph_1.png",panel,height=3.5,width=7,dpi=300)

```

```
knitr::include_graphics("graph_1.png")
```

```
# Run a 3-way ANOVA to analyze your variables:
```

```
a <- anova_test(data = long_data, dv = value, within = variable, wid = ID, between = c
get_anova_table(a)
```

```
## ANOVA Table (type III tests)
```

```
##
##          Effect DFn DFd      F      p p<.05 ges
## 1          age_cat    1   81  7.917 0.006  * 0.043
## 2           Drug     1   81  3.576 0.062    0.020
## 3        variable     1   81  0.401 0.528    0.003
## 4    age_cat:Drug     1   81  7.639 0.007  * 0.042
## 5 age_cat:variable     1   81  1.263 0.264    0.008
## 6   Drug:variable     1   81  6.808 0.011  * 0.043
## 7 age_cat:Drug:variable 1   81  1.892 0.173    0.012
```

- There is a significant main effect of age ($F(1,81) = 7.92$, $p = 0.006$).
- There is a significant interaction between age and drug treatment ($F(1,81) = 7.64$, $p = 0.007$).
- There is a significant interaction between drug treatment and time of testing ($F(1,81) = 6.81$, $p = 0.01$).
